Horsthemke, B., Beisiegel, U., Dunning, A., Havinga, J.R.,

Williamson, R. and Humpfries, S.

Unequal crossing-over between two alu-repetitive DNA sequences in the low-density-lipoprotein-receptor gene. A possible mechanism for the defect in a patient with familial hypercholesterolaemia

Bur. J. Blochem. 164 (1), 77-81 (1987)
                                                                                                                                                                                                                                                                                      See X05250 for corresponding normal gene sequence. In the defective LDL-receptor gene the deletion ocurred between two alu-repetitive sequences, that are in the same direction, the deletion eliminates exons 13 and 14 and changes the reading frame of the resulting spliced mRNA.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 *Source: hypercholesterol aemia
See X05248 for corresponding normal gene sequence
In the defective LDL-receptor gene the deletion ocurred between two
allu-repetitive sequences, that are in the same direction, the
deletion eliminates exons 13 and 14 and changes the reading frame
of the resulting spliced mRNA.

The GS (Gene Signature) sequences were obtained from 3'-directed cDNA was initiated from the Cs from various human tissues; synthesis of CDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-c untranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be cetermined (ssp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types.

double-stranded DNA, which comprises one of the 7837 "GS" sequences double-stranded DNA, which comprises one of the 7837 "GS" sequences given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mNAM is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA libraries prepared from various human tissues; synthesis of cDNA was inlitated from the 3'-end of mNAM by using poly(T) as the sole primer. Since the 3'-tuntranslated sequence; unitanslated sequence is unique to a particular mNAM species, almost all the 3'-oriented cDNAs hybridise with specific mNAMs. Each library is constructed so as to reflect accurately the relative abundance of different mNAMs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for sequence 103 BP; 22 A; 27 C; 21 G; 31 T;
                                                                                                                                                                                                                                                                                                                                                                                                          9846 CATGGTGAAACCCTGTCTCTACTAAAAATACAAAAATTAGCCGGGCATGGTGGTGCACGC 9905

determining polymorphic forms for use in e.g. forensics, paternicy determining polymorphic typing for disease

Claim 1. Page 219; 310pp; English.

X10269-X12937 are human DNA fragments which contain biallelic polymorphic markers which have been isolated using the primers represented in markers which have been isolated using the primers represented in markers which have been isolated using the primers represented in care appropriate IUPAC-IUB ambiguity code. These fragments can be used in methods for determining polymorphic forms in an individual for use in methods for determining polymorphic forms in an individual for use in caton a sagammagalobulinmanta, diabetes insiphdua, feach Nyhan syndrome, cuch as agammagalobulinmanta, diabetes insiphdua, feach Nyhan syndrome, papercholesterolemia, polycystic kidney disease, hereditary hamorrhagic telangiectasia, familial colonic polyposis, Bhiers-banlos syndrome, osteogenesis imperfecta, acute intermittent porphyria.

Syndrome, osteogenesis imperfecta, acute intermittent porphyria, autolimune diseases, inflammation, cancer, diseases of the nervous system, infection by pathogenic microorganisms, and characteristics such as longevity, appearance (e.g. baldness, obesity), strength, speed, endurance, fertility, and susceptibility or receptivity to particular drugs or therapeutic treatments. The isolated polymorphic nucleic acid grugs or therapeutic treatments. The isolated polymorphic or correspondence.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              22775 GAGGCTCTTGCCTGTAATCCCAGCACTTTGGGAGGCCGAGGAGGAGGATGGCTTGAGCC 22834

                                                                             While year Sangery A.2.

New isolated nucleic acid segments from the human genome - used for determining polymorphic forms for use in e.g. forensics, paternity resting or phenotyphic typing for disease

Election 1, Page 218; 310pp; English.

Claim 1, Page 218; 310pp; English.

Claim 1, Page 218; 310pp; English.

Claim 1, Page 218; 310pp; English.

CC markers which have been isolated using the primers represented in the perpendicular of the perpendicular of the primers represented in the control of the appropriate IUPAC-IUB ambiguity code. These fragments can be used in the appropriate IUPAC-IUB ambiguity code. These fragments can be used in the complex for determining polymorphic forms in an individual for use in the code of as agammagiobulinemia, diabetes insipidus, Lesch-Nyhan syndrome, code as agammagiobulinemia, diabetes insipidus, Easch-Nyhan syndrome, such as agammagiobulinemia, polycystic kidney disease, hereditary spherorolesterolemia, polycystic kidney disease, colonic polyposis, Ehers-Danlos syndrome, osteogenesis imperfecta, acute intermittent porphyria, autoimmune diseases, inflammation, cancer, diseases of the nervous system, infection by pathogenic microorganisms, and characteristics such as longevity, appearance (e.g. baldness, obesity), strength, speed, endurance, fertility, and susceptibility or receptivity to particular drugs or therapeutic treatments. The isolated polymorphic nucleic acid copyphylaxis of such diseases.

C prophylaxis of such diseases.

A single-stranded DNA (or its complementary strand or the corresp. double-stranded DNA) which comprises one of the 7837 "GS" sequences double-stranded DNA) which comprises one of the 7837 "GS" sequences could be stranded DNA) which comprises one of the 7837 "GS" sequences obtained from 3'-directed cDNA libraries prepared from arious human tissues; synthesis of cDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-entranslated sequence is unique to a particular mRNA species, almost untranslated course of the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types. 21 C; 25 G; 23 T;

3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-untranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types.

```
A single-stranded DNA (or its complementary strand or the corresp. A single-stranded DNA (or its complementary strand or the corresp. double-stranded DNA) which comprises one of the 7837 "GS" sequences of given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, CDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed CDNA hibraries prepared from various human tissues; synthesis of CDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-entranslated sequence is unique to a particular mRNAs pecies, almost is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for sequence 99 BP; 43 A; 18 C; 16 G; 22 T;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           15706 CAGTTTTTTTTTTTTTTTTTTTTTTTTTTTTTTTTTTGAGACAGAGTCTCACTCTATCACC 15765
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Claim 1; Page 758-759; 2245pp; Japanese. A single-stranded DNA (or its complementary strand or the corresp. double-stranded DNA) which comprises one of the 7837 "GS" sequences given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA libraries prepared from various human tissues; synthesis of cDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-untranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Human gene signature HUMGS02180.
Gene signature: messenger RNA; mRNA; relative abundance; frequency; human; cloning; mapping; non-biased library; diagnosis; detection; cell typing; abnormal cell function; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      double-stranded DNA, which comprises one of the 7837 "GS" sequences double-stranded DNA, which comprises one of the 7837 "GS" sequences given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA libraries prepared from various human tissues; synthesis of cDNA was initiated from the 3'-c untranslated sequence; synthesis of cDNA was initiated from the 3'-c untranslated sequence; sundque to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for sequence 108 BP; 18 A; 33 C; 28 T;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               10897 GATCTCCTGACCTCGTGATCCACCCGCTTTGGCCTCCCAAAGTGCTGGGATTACAGGCGT 10956

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             A single-stranded DNA (or its complementary strand or the corresp. double-stranded DNA) which comprises one of the 7837 "Gs" sequences given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA libraries prepared from various human tissues; synthesis of cDNA libraries prepared from various human tissues; synthesis of cDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-untranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was delived.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            90 TGAGACAGNNICTCACGCTGTCACCNAGGCTGGAGCGCAGGAGTGCCATCTCAGCTCACT 31

WO9514772-A1.
is constructed so as to reflect accurately the relative abundance of different marks in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types. 27 C; 21 G; 31 T;

A single-stranded DNA) which complementary strand or the corresp.

A single-stranded DNA) which comprises one of the 7837 "GS" sequences double-stranded DNA) which comprises one of the 7837 "GS" sequences.

G given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3 '-directed cDNA hibraries prepared from various human tissues; synthesis of CDNA was initiated from the 3 '-end of mRNA by using poly(T) as the sole primer. Since the 3'-cuntranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed as oas to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types.

Claim 1; Page 1748; 2245pp; Japanese.

A single-stranded DNA (or its complementary strand or the corresp.

Couble-stranded DNA, which comprises one of the 7837 "65" sequences

Given in T19001-T26837 and which is able to hybridise to part of

human genomic DNA, CDNA or mRNA is claimed. The GS (Gene Signature)

sequences were obtained from 3'-directed cDNA libraries prepared

from various human tissues; synthesis of cDNA was initiated from the

circum various human tissues; synthesis of cDNA was initiated from the

circum various human poly(T) as the sole primer. Since the 3'-

untranslated sequence is unique to a particular mRNA species, almost

all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library

is constructed so as to reflect accurately the relative abundance of

different mRNAs in the particular tissue from which it was derived.

The appearance frequency of a given GS in a cDNA library can be

determined (esp. using primers and probes derived from the GS

recognising different cell types.

Sequences) as a means of diagnosing abnormal cell function or for

recognising different cell these.
Matsubara K, Okubo K;
WPI: 95-206931/27.
Identifying gene signatures in 3'-directed human cDNA library - e.g.
for diagnosis of abnormal cell function, by preparing cDNA that
reflects relative abundance of corresp. mRNA in specific human
                                                                                                                                                          tissues

Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  SUMMARIES

/note="Vector: pAMP10; cDNA was generated from cytoplasmic RNA using a mixture of random DNA hexamers and oligo(dT).
From this pool of cDNA, human chromosome 7-enriched cDNA was isolated by direct cDNA selection using chromosome 7
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Genome Technology Branch

/note="Vector: pT7T3D-Pac (Pharmacia) with a modified polylinker: 1st strand cDNA was prepared from 3 pooled germ cell tumors, and was then primed with a Not I oligo(dT) primer. Double-stranded cDNA was ligated to Eco RI adaptors (Pharmacia), digested with Not I and cloned into the Not I and Eco RI sites of the modified pT7T3 vector. Library is not normalized. Library was constructed by Bento Soares and M. Fatima Bonaldo. "

Patent No. 5948888
GENERAL INFORMATION:
GENERAL INFORMATION:
APPLICANT: Wands, Jack R.
TITLE OF INVENTION: Neural Thread Protein Gene Expression and Detection
TITLE OF INVENTION: of allaheimer's Disease
NUMBER OF SEQUENCES: 121
CORRESPONDENCE ADDRESS:
                                                                                                                 Protein Gene Expression and Detection
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   10875 CCATGTTAGCCAGGATGGTCTCGATCTCCTGACCTCGTGATCCACCCGCTTTGGCCTCCC 10934

Horsthemke, B., Beisiegel, U., Dunning, A., Havinga, J.R., Williamson, R. and Humphries, S.
Unequal crossing-veer between two alu-repetitive DNA sequences in the low-density-lipoprotein-receptor gene. A possible mechanism for the defect in a patient with familial hypercholesterolaemia

Eur. J. Blochem. 164 (1), 77-81 (1987)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     See X05248 for corresponding normal gene sequence In the defective LDL-receptor gene the deletion courred between two alu-repetitive sequences, that are in the same direction, the deletion eliminates exons 13 and 14 and changes the reading frame of the resulting spliced MRN.

see X05250 for corresponding normal gene sequence
In the defective LDL-receptor gene the deletion ocurred between two
allu-repetitive sequences, that are in the same direction, the
deletion eliminates exons 13 and 14 and changes the reading frame
of the resulting spliced mRNN.

Williamson, R. and Humphries, S.
Unequal crossing-over between two alu-repetitive DNA sequences in the low-density-lipoprotein-receptor gene. A possible mechanism for the defect in a patient with familial hypercholesterolaemia

Eur. J. Blochem. 164 (1), 77-81 (1987)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               See X05250 for corresponding normal gene sequence. In the defective LDL-receptor gene the deletion ocurred between two alu-repetitive sequences, that are in the same direction, the deletion eliminates exons 13 and 14 and changes the reading frame

A single-stranded DNA, Or its complementary strand or the corresp.

double-stranded DNA, which comprises one of the 7837 "GS" sequences
given in T19001-T25837 and which is able to hybridise to part of
human genomic DNA, CDNA or mRNA is claimed. The GS (Gene Signature)
sequences were obtained from 3'-directed cDNA libraries prepared
from various human tissues; synthesis of cDNA was initiated from the
3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-
untranslated sequence is unique to a particular mRNAs pecies, almost
all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library
is constructed so as to reflect accurately the relative abundance of
different mRNAs in the particular tissue from which it was derived.
The appearance frequency of a given GS in a cDNA library can be
determined (esp. using primers and probes derived from the GS
sequences) as a means of diagnosing abnormal cell function or for

A single-stranded DNA (or its complementary strand or the corresp. double-stranded DNA) which comprises one of the 7837 GS* sequences given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA libraries prepared from various human tissues; synthesis of cDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-untranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Beach library
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           30-MAR-1999 (first entry)

Human biallelic polymorphic DNA fragment TIGR-A003M18a.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types. 2 C; 25 G; 22 T;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      A single-stranded DNA which complementary strand or the corresp.

A single-stranded DNA which comprises one of the 7837 "GS" sequences couble-stranded DNA, which comprises one of the 7837 "GS" sequences and missing the complementary strand couple of part of human genomic DNA, CDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed CDNA libraries prepared to manna risussing poly(T) as the sole primer. Since the 3'-cuntranslated sequence is unique to a particular mRNA species, almost intranslated sequence is unique to a particular mRNA species, almost is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   7549 CTGTAATCCCAGCAC-TTTGGGAGGCTGAGGTGGATCACCTGAGGTTGGGAGTTTG 7607

double-stranded DNA, or its complementary strand or the corresp.

double-stranded DNA, which comprises one of the 7837 "GS" sequences given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA libraries prepared from various human tissues; synthesis of cDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-cuntranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for sequence 91 BP; 18 A; 22 C; 28 G; 18 T;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 4066 ATCACTTAAACTCAGGAGGCAGAGGTTGCAGTGAGCTGAGATCACACCATTGCACTCCAG 4125

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           While you soluted nucleic acid segments from the human genome - used for determining polymorphic forms for use in e.g. forensics, paternity resting or phenotypic typing for disease

Claim 1: Page 219; 310pp; English.

Claim 1: Page 219; 310pp; English.

X10269-X12937 are human DNA fragments which contain biallelic polymorphic markers which have been isolated using the primers represented in X09121-X10268. The base occupying the polymorphic site is indicated by the appropriate IUPAC-IUB ambiguity code. These fragments can be used in methods for determining polymorphic forms in an individual for use in e.g. forensics, paternity testing or for phenotypic typing for diseases such as agammaglobulinemia, diabetes insipidus, Lesch-Nyhan syndrome, mascular dystrophy, Wiskott-Aldrich syndrome, Pabry's disease, familial hypercholesterolemia, polycystic kidney disease, hereditary spherocytosis, von Willebrand's disease, tuberous sclerosis, hereditary syndrome, osteogenesis inmerfected, acute internitent porphyria, autolimmune diseases, inflammation, cancer, diseases of the nervous syndrome, osteogenesis inflammation, cancer, diseases of the nervous system, infection by pathogenic microorganisms, and characteristics such as longerity, appearance (e.g. baldness, obseitly), strength, speed, canturance, fertility, and susceptibility or receptivity to particular drugs or therapeutic treatments. The isolated polymorphic nucleic acid converted and the converted medicaments for the treatment or prophyriane.
                                                                                                                  ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                ij

                                                                                                                                                                                                                                                                                                                                                                                                                                                             ö
                                                                 A single-stranded DNA) which complementary strand or the corresp.

A single-stranded DNA) which comprises one of the 7837 "GS" sequences given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA was intriated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-en of or mRNA by using poly(T) as particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library call the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed as oa st or reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for seconising different cell types.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         A single-stranded DNA (or its complementary strand or the corresp. A single-stranded DNA) which comprises one of the 7837 "GS" sequences double-stranded DNA) which comprises one of the 7837 "GS" sequences given in Tig001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA libraries prepared from warious human tissues; synthesis of cDNA was initiated from the 3'-end of mRNA by using poly!(") as the sole primer. Since the 3'-untranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived. The appearance frequency of a given GS in a cDNA library can be determined (esp. using primers and probes derived from the GS sequences) as a means of diagnosing abnormal cell function or for recognising different cell types.

A single-stranded DNA (or its complementary strand or the corresp. A single-stranded DNA (or its complementary strand or the corresp. double-stranded DNA) which comprises one of the 7837 GS" sequences given in T19001-T26837 and which is able to hybridise to part of human genomic DNA, cDNA or mRNA is claimed. The GS (Gene Signature) sequences were obtained from 3'-directed cDNA libraries prepared from various human tissues; synthesis of CDNA was initiated from the 3'-end of mRNA by using poly(T) as the sole primer. Since the 3'-untranslated sequence is unique to a particular mRNA species, almost all the 3'-oriented cDNAs hybridise with specific mRNAs. Each library is constructed so as to reflect accurately the relative abundance of different mRNAs in the particular tissue from which it was derived.
